Victoria University of Wellington*

The WHILE Language

test.while

```
type Point is {int x, int y}
```

```
Point move(Point p, int dx, int dy) {  
    return {x: p.x + dx, y: p.y + dy};  
}
```

- A **simple** imperative language
- **Statements**: for, while, if, switch, ...
- **Expressions**: binary, unary, invocation, ...
- **Types**: bool, int, arrays, records, unions, ...

Primitive Types

```
bool f2 () { return false; }
```

```
int f3 () { return 'X'; }
```

```
int f4 (int x) { return x + 1; }
```

```
int[] f6 () { return "Hello World"; }
```

- `bool` — true or false
- `int` — 32bit signed integers (identical to Java `int`)
- `string` — array `ints` representing ASCII characters (not unicode, for simplicity)

Record Types

```
{int x, int y} Point(int x, int y) {  
    return {x: x, y: y}; // record construction  
}  
  
int getX({int x, int y} p) {  
    return p.x; // field access  
}  
  
{int x, int y} setX({int x, int y} p, int v) {  
    p.x = v; // field assignment  
    return p;  
}
```

- Similar to `structs` in C and objects in Java and/or JavaScript
- Support **width** and **depth** subtyping (more on this later)

Array Types

```
int[] trim(int[] xs, int n) {
    int[] rs = [0; n]
    int i = 0;
    while (i < |rs|) {
        rs[i] = xs[i];
        i = i + 1;
    }
    return rs;
}
```

- Similar to **arrays** in C and Java, but have **value** semantics
- Support *array access* (`xs[i]`) and *array length* (`xs||`)
- Support *array initialisers* (`[1, 2, 3]`) and *generators* (`[0; n]`)

Union Types

```
// Return first index which matches c, or null if no match.  
int | null indexOf(int [] str, int c) {  
    for(int i=0; i!=|str|; ++i) {  
        if(str[i] == c) {  
            return i; // matched  
        }  
    }  
  
// didn't find a match  
    return null;  
}
```

- The type containing both T1 and T2 is T1 | T2
- Allow the composition of data types
- Similar to unions in C

Type Declarations

```
type Point is {int x, int y}
```

```
type Line is {Point start, Point end}
```

- Can declare **new types** via `type`
- Types are **structural** and cannot be **recursive**
- Types can refer to types declared **earlier** in source file
- Should regard such declarations as **macros**
- E.g. `{{int x, int y} start, {int x, int y} end}`

Statements

```
int[] toString(int c) {  
    switch(c) {  
        case 1:  
            return "ONE";  
        case 2:  
            return "TWO";  
        case 3:  
            return "THREE";  
        default:  
            return "";  
    }  
}
```

- Support `if`, `while`, `for`, `return`, `switch`
- Syntax is roughly same as for Java

Expressions

- **Constants:** `1`, `2345`, `true`, `false`, `"hello"`
- **Comparators:** `==`, `!=`, `<`, `<=`, `>=`, `>`
- **Arithmetic:** `+`, `-`, `*`, `/`, `%`
- **Logical:** `!`, `&&`, `||`
- **Arrays:** `[1, 2, 3]`, `[e; n]`, `xs[i]`, `|xs|`
- **Records:** `|x: 1, y: 2|`, `r.f`
- **Invocations:** `f(1, 2, 3)`

Value Semantics

```
int [] inc(int [] xs) {  
    for(int i=0;i!=|xs|;i=i+1) { xs[i] = xs[i] + 1; }  
    return xs;  
}
```

```
void f() {  
    int [] xs = [1,2,3];  
    int [] ys = inc(xs);  
    assert xs == [1,2,3];  
    assert ys == [2,3,4];  
}
```

- All data types have **value semantics**
- They are **passed by value**, and updates to them **do not affect** other variables

Definite Assignment

```
int f() {  
    int x;  
    return x+1;           // error  
}
```

```
int f(int y) {  
    int x;  
    if (y == 1) { x = 1; }  
    return x;           // error  
}
```

- Every variable must be **defined** before it is used!
- Simple (conservative) analysis used to check this (see JLS §16)

Unreachable Code

```
int f() {  
    return 1;  
    return 2; // error  
}
```

```
int f(int y) {  
    if (y == 1) { return 1; }  
    else { return 2; }  
    return 3; // error  
}
```

- Code which is **unreachable** is not permitted (see JLS §14.21)
- Simple (conservative) analysis used to check this.

Type Checking

```
int f(int [] xs) { return xs; } // error
```

```
void f(bool x) { int y = x; } // error
```

```
bool f(int x, bool y) { return x + y; } // error
```

```
type Point is {int x, int y}
```

```
bool f(Point p) { return p.x; } // error
```

- The process of checking a program is **well-typed**

Subtyping

Definition (Structural Subtyping)

We write $T_1 \leq T_2$ to indicate T_1 is a *subtype* of T_2 . If $\llbracket T \rrbracket$ is the set of all values represented by T , then $T_1 \leq T_2 \iff \llbracket T_1 \rrbracket \subseteq \llbracket T_2 \rrbracket$

- **Void** is bottom (e.g. `void` \leq `int`)
- **Covariant** array subtyping (e.g. `void[]` \leq `int[]`)
- **Width** subtyping of records (e.g. `{int x, int y}` \leq `{int x}`)
- **Depth** subtyping of records (e.g. `{void[] x}` \leq `{int[] x}`)

Note: *Covariant array subtyping is safe in WHILE because arrays have value semantics, unlike Java where it is unsafe.*

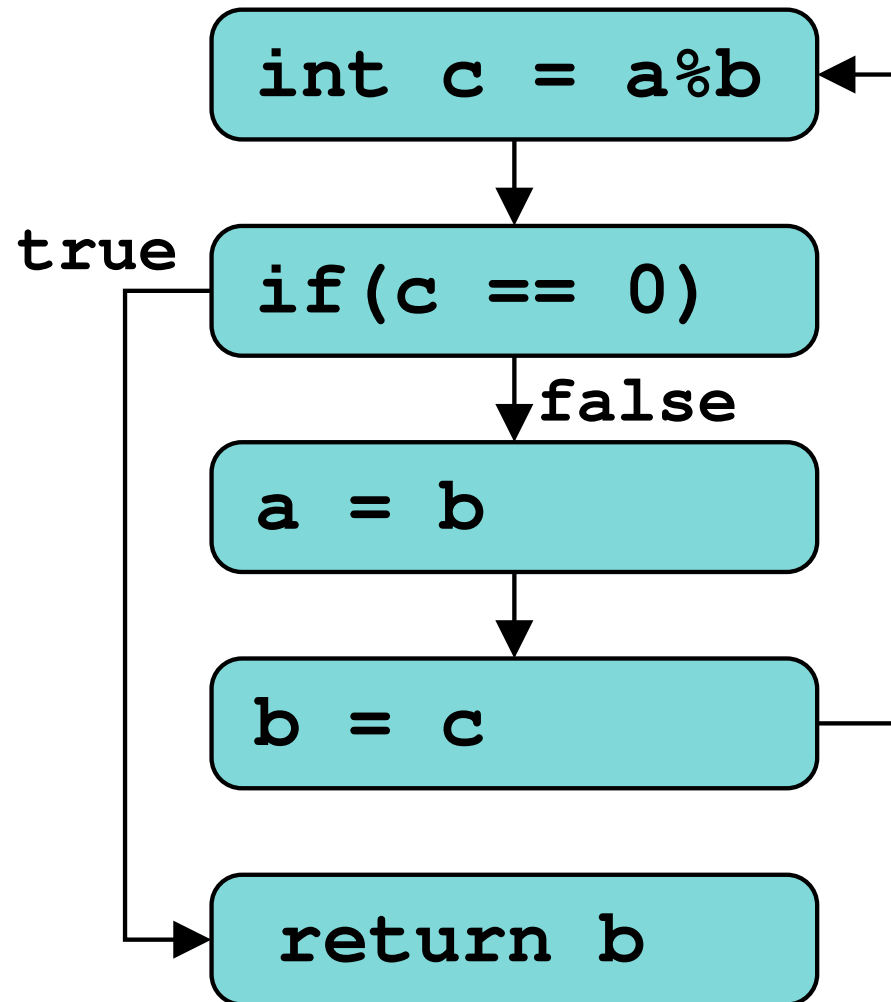

Type Tests + Casts

```
type nint is null | int

int f(nint ni) {
  if(ni is int) {
    int i = (int) ni;
    return i;
  } else { return 0; }
}
```

- Type tests are similar to `instanceof` in Java
- Casts needed to **convert types** after type tests
- **Flow typing** is not supported (unlike Whaley)

Control-Flow Graph (CFG)

- Every WHILE program representable as a **control-flow graph**

(No) Function Overloading

```
int f(int x) {  
    return 42;  
}  
  
int f(int [] xs) { // error  
    return 42;  
}
```

- Java supports **function overloading**, but WHILE does not
- This eliminates problem of determining which **function called**
- Could be added, but we'd need to use **name mangling**
